Executive Summary

The Yuma clapper rail (*Rallus longirostris yumanensis*) is a federally endangered species and 90% of the U.S. population exists in only 2 wetlands associated with the Lower Colorado River. The California black rail (*Laterallus jamaicensis coturniculus*) is another sensitive species of national management concern that occurs in this region. Historically, marsh habitats along the lower Colorado River were highly ephemeral with periodic flooding and natural fires which eliminated decadent stands of emergent vegetation. Years of flood control and fire suppression has resulted in substantial areas of decadent emergent marsh habitat. To ensure long-term persistence of the Yuma clapper rail and California black rail, we examined the effectiveness of prescribed fire as a possible management tool to restore habitat for these 2 species. Numbers of Yuma clapper rails and California black rails increased significantly following fire in burned sites compared to control sites. Increases were apparent in the first year following fire for clapper rails and in year 2 post-fire for black rails. As a result of the field protocols developed for this project, we initiated a national program for monitoring marsh birds and for evaluating the effects of management actions on marsh birds. The protocols developed by this project are being used by over 100 field offices representing 40 state and federal land management agencies. Products from this study are available on the project webpage: www.ag.arizona.edu/snr/research/coop/azfwru/fire_effects_on_rails.

Introduction

The Yuma clapper rail (*Rallus longirostris yumanensis*) is a federally endangered species that occurs along the lower Colorado River, in the Imperial Valley of California, in the Colorado River Delta, and along the west coast of Mexico. Ninety percent of the U.S. population exists in only 2 wetlands (Conway et al. 1993) and much existing wetland habitat remains unoccupied. To ensure long-term persistence of U.S. populations, we need to have effective management and mitigation activities that improve habitat quality and benefit Yuma clapper rail populations. One possible management activity that has been proposed to benefit Yuma clapper rail populations is prescribed burning in areas with decadent emergent vegetation (Conway et al. 1993).

Historically, marsh habitats along the lower Colorado River were highly ephemeral with periodic flooding and natural fires eliminating decadent stands of emergent vegetation. These stochastic events resulted in areas of early successional emergent marsh habitat thought to be beneficial to rails (Conway 1990, Conway et al. 1993). Years of flood control and fire suppression has resulted in substantial areas of decadent emergent marsh habitat and very little early successional emergent marsh along the lower Colorado River. Prescribed fire may be the best technique for creating early-successional emergent marsh habitat required to enhance populations of Yuma clapper rails. Indeed, prescribed fire has been repeatedly suggested as a promising conservation measure for restoring Yuma clapper rail populations (Conway et al. 1993, Conway 1995, Eddleman and Conway 1998, Conway and Eddleman 2000), but has yet to be evaluated.

The California black rail (*Laterallus jamaicensis coturniculus*) is another sensitive species of national management concern that may simultaneously benefit from prescribed burning. California black rails are listed as state endangered in Arizona (Arizona Game and Fish

Department 1988), state threatened in California (California Department of Fish and Game 1989), and federally endangered in Mexico. Black Rails are also considered a species of national conservation concern in the U.S. (U.S. Fish and Wildlife Service 2002), are on the National Audubon Society's "WatchList", and were once a Category 1 "candidate" species for federal listing under the Endangered Species Act (U. S. Dept. of Interior 1989). The lower Colorado River is one of three areas remaining with a moderate breeding population of California black rails (Evens et al. 1991, Conway et al. 2001). Hence, active on-the-ground habitat restoration efforts to specifically benefit California black rails on the lower Colorado River should begin now in an effort to recover populations and prevent federal ESA listing.

The effects of fire on California black rails are not known, and opinions are equivocal. Repking (1975) suggested fire be investigated as a possible management tool for California black rails, but Todd (1980) cautioned that regrowth of common threesquare (*Schoenoplectus pungens*), a wetland plant commonly associated with black rails, may not occur fast enough and may be eliminated completely by fire. Areas with three-square bulrush may burn hotter and regrowth may occur at a slower pace compared to cattail in the wetter portions of a marsh (Todd 1980). This project will help determine whether or not fire is beneficial to California black rails.

We conducted pre- and post-burn surveys in both burned and control marshes to examine the effects of fire on the abundance of rails and the quality of rail habitat. This project addresses the goals of the Lower Colorado River Multi-species Conservation Plan (LCR MSCP). Both the Yuma clapper rail and California black rail are considered priority species of concern in the LCR MSCP and goals for both species include the enhancement of existing habitat, restoration of unsuitable habitat, and the establishment of additional breeding locations on the LCR.

Field Locations

Study Sites were located along the lower Colorado River in Arizona (Yuma County) and California (Imperial County), and south of the Salton Sea in the Imperial Valley of California (Imperial County). We worked closely with Imperial National Wildlife Refuge, Havasu National Wildlife Refuge, and Sony Bono Salton Sea National Wildlife Refuge to conduct burns and marsh bird surveys at each refuge. We also surveyed marshes on other state and federally owned lands. See Tables 1-2 for a summary of each study site.

Methods

We conducted call-broadcast surveys for both species of rails in 4 types of study sites: sites recently burned by wildfire ($n=7$), non-burned (control) sites near each wildfire ($n=14$), sites recently burned by prescribed fire ($n=19$), and non-burned (control) sites near each prescribed burn ($n=24$) (Tables 1-2). At each study site, we conducted at least 3 replicate surveys from March-July in years pre- and post-fire. Hence, we had both temporal (pre-burn vs. post-burn) and spatial (burned and unburned) controls built into the study design, providing a rigorous evaluation of the usefulness of fire for marsh management and restoration of Yuma clapper rails and California black rails.

We worked closely with Bureau of Land Management and U.S. Fish and Wildlife Service fire crews to have burns conducted for this study. We developed survey protocols based on our previous studies of marsh bird survey methods (Conway et al. 1993, Conway and Gibbs 2001,

Conway et al. 2001) and on recommendations from a recent wetland bird monitoring workshop at the USGS Patuxent Wildlife Research Center (Ribic et al. 1999). Surveys were conducted during mornings between one half-hour before sunrise until 10:00 am and in the evenings between 5:00 pm until dusk (one half-hour after sunset). All surveys were conducted on days without rain and when wind speeds did not exceed 5 mph. Based on previous marsh bird survey work in the region, conditions during most (99%) mornings are favorable for surveys (i.e., without too much wind) whereas 42% of evenings are too windy for surveys. All surveyors attended 2 weeks of extensive field training, and each surveyor took a hearing test (audiogram) to check their ability to hear subtle bird vocalizations. We used repeated measures analysis of variance to examine whether fire increased abundance of rails.

Results

Numbers of Yuma clapper rails increased following fire and abundance was higher compared to control sites in the 2 years post-burn (Fig. 1). Numbers of California black rails increased following fire and abundance was higher compared to control sites in years 2 and 3 post-burn (Fig. 2). During the course of developing the field protocols for this project, we saw a need to make our field protocols available to land management agencies across the country. Hence, we developed a stand-alone set of field protocols for use by others so that data could be pooled across the country to examine the effects of fire (and other management actions) on secretive marsh birds. This subsequently led to the development a national program for monitoring marsh birds. The protocols developed by this project are being used by over 100 field offices representing 40 state and federal land management agencies. Several of these field offices are using our field protocols to examine fire effects. Products produced from this study are listed in Appendix 1 and 2, and many of these are available on the project's webpage (www.ag.arizona.edu/snr/research/coop/azfwru/fire_effects_on_rails).

Acknowledgments

The project is funded by Joint Fire Science Program with additional funding provided by U.S. Bureau of Reclamation, Sonoran Joint Venture, Imperial National Wildlife Refuge, and USGS-USFWS Science Support Program. Imperial National Wildlife Refuge provided temporary field housing, field vehicles, and a boat for our field personnel; we thank Ken Edwards, Greg Birkenfeld, Jackie Ferrier, and Guy Wagner for their support and assistance. Sonny Bono-Salton Sea National Wildlife Refuge also provided temporary housing for the project; we thank Chris Schonomen for his support of the project. Havasu National Wildlife Refuge provided temporary field housing and use of a boat; we thank Greg Wolf, John Earle, Jack Allen, and Aimee Haskew for their support and assistance. Bureau of Reclamation, Boulder City provided a boat for our field surveys and we thank Greg Finnegan for assistance with the boat and trailer. BLM and USFWS fire crews planned and conducted prescribed fires. Carl Olsen from the University of Arizona Entomology Museum provided assistance and training in identification of invertebrates. Other personnel working on the project included Michael Vamstad, Amy Stabler, Heather Cara Stutzman, Sian Wallace, Paul Sweet, Augustus Keck, Nick Bartok, Roberta Montano, Nick Mannan, Erik Meyer, Meaghan Conway, Archer

Larned, and Jake Mohlman. We obtained USFWS permits to conduct call-broadcast surveys for Yuma Clapper Rails (permit # TE039466-0). We also obtained the necessary permits from the Institutional Animal Care and Use Committee at the University of Arizona.
